Extended Data Fig. 12 | Top100 and top200 gene overlap and enrichment

Top row, Gene overlap and enrichment for nine-configuration top100 lists (99–100 mapped genes per list; 519 distinct mapped genes). Middle row, Corresponding top200 results (198–200 mapped genes per list; 809 distinct mapped genes). Metascape used human Entrez mapping (database 2026-07-01), a whole-genome background, $P < 0.01$, at least three hits and enrichment factor > 1.5; q-values use Benjamini-Hochberg correction. Purple chords link identical mapped genes; dark/light orange denotes shared/list-specific genes. Heatmaps retain each report's 20 representative clusters, independent clustering and -log10(P) scale; grey denotes zero/no enrichment in the supplied matrix. List definitions differ across methods. biVI ranks Radial Glia-versus-other-cell norm_spliced_mean differential results by Bayes factor, including both LFC signs; this is not a direct velocity-gene ranking. These are descriptive gene-list comparisons, not method-accuracy tests. Bottom row, Historical young and aged ReDeeM LatentVelo fields, respectively, using the reported 784 shared genes; these are separate from the forebrain enrichment analyses. The exact 784-gene manifest and matching run remain unresolved. No new aging comparison or velocity model fitting was performed.
